

Image Analysis Made Easy with
ImageStream Cytometry

April 27, 2011

Thaddeus George, Ph.D.

Director of Biology

Amnis Corporation

The ImageStream[®] System

High speed imaging (ImageStream[™])

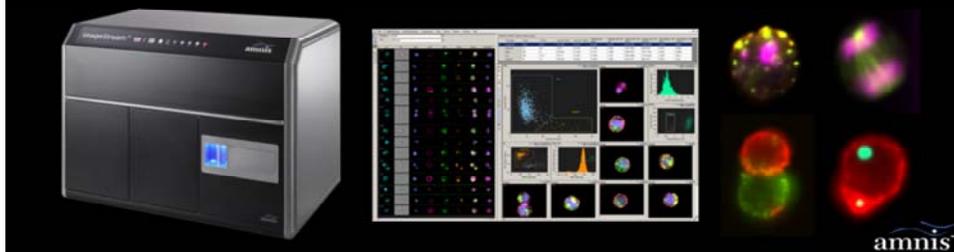

+

Quantitative image analysis (IDEAS[®])

=

Advances your research

But WHY???

Key advantages over microscopy:

- 1 – objective image collection (avoids selection bias)
- 2 – high speed (provides statistics even for rare events)
- 3 – simultaneous multispectral imaging (avoids requirement to take sequential pictures of each cell)
- 4 – quantification of imagery by IDEAS (provides standard objective repeatable measurements of imagery)

Key advantages over flow cytometry:

- 1 – high information content provided by images (features related to size, shape, texture, location, co-location)
- 2 – images linked to quantitative features (can see the cell when you click on a dot)

The ImageStream[®] System

High speed imaging (ImageStream[™])

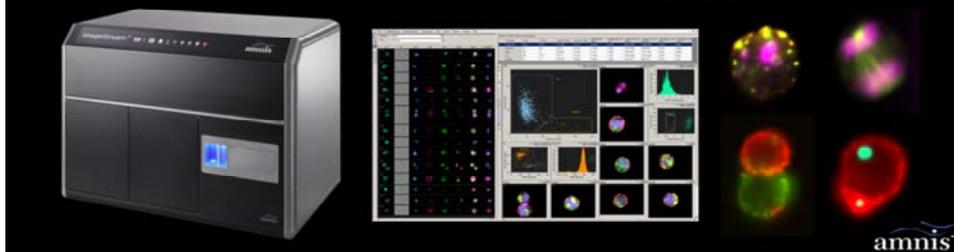

+

Quantitative image analysis (IDEAS[®])

=

Advances your research

Because you can discriminate cells
objectively and *statistically* based on their appearance

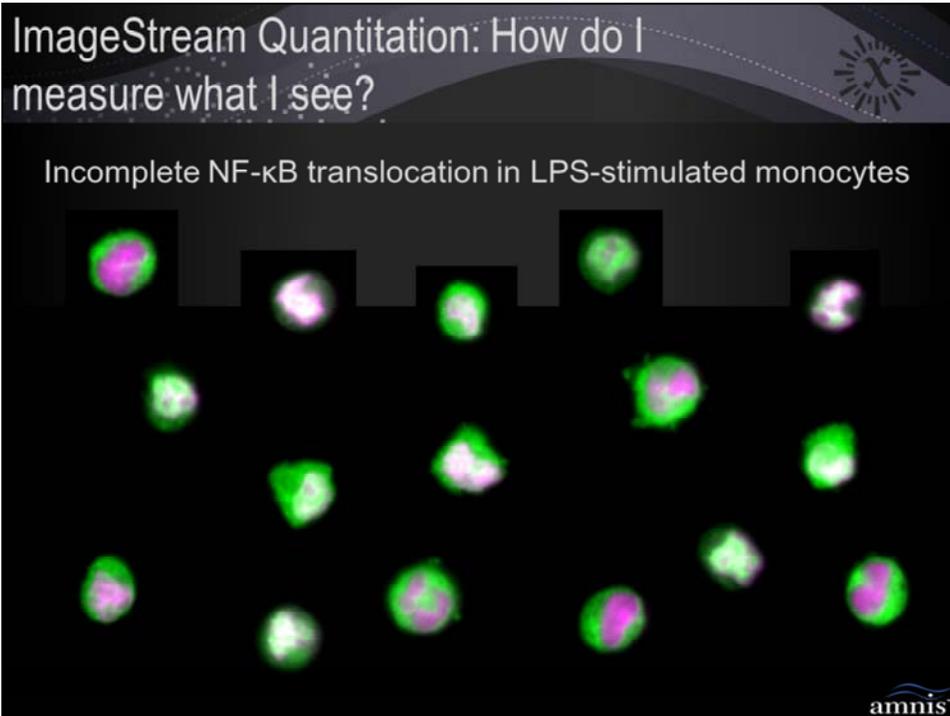

Key advantages over microscopy:

- 1 – objective image collection (avoids selection bias)
- 2 – high speed (provides statistics even for rare events)
- 3 – simultaneous multispectral imaging (avoids requirement to take sequential pictures of each cell)
- 4 – quantification of imagery by IDEAS (provides standard objective repeatable measurements of imagery)

Key advantages over flow cytometry:

- 1 – high information content provided by images (features related to size, shape, texture, location, co-location)
- 2 – images linked to quantitative features (can see the cell when you click on a dot)

These are human monocyte line THP-1 cells treated with an intermediate dose of LPS to activate nuclear translocation of NFκB, then stained with FITC NFκB (green) and 7-AAD (nuclear dye, red). The imagery shows that the population contains cells that span a continuum from the untranslocated to the translocated state.

Qualitative analysis is difficult: someone expecting translocation and another person expecting inhibition of translocation will both see cells that meet their expectations...

Manually quantifying this sample would require observation and scoring of many cells – too time consuming and subjective to feasibly perform quantitative analysis. Also note that the nucleus occupies most of the cell, and the cells and nuclei are irregular, making it difficult to accurately quantify the amount of NFκB in the cytoplasmic and nuclear compartments.

Bio2:\2010 Data\061410 X101 THP-1 NFκB 60X 40X Mag EDF

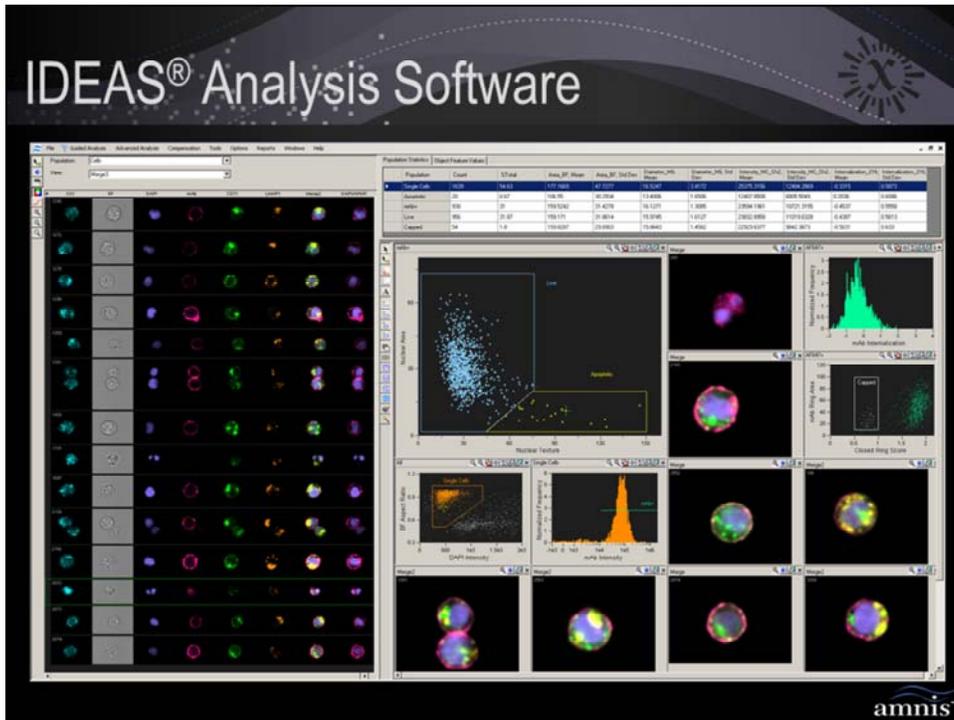

ImageStreamX

- 1,000 cells per second
- 12 image channels per cell: SSC, brightfield, fluorescent
- Up to 5 lasers (488, 405, 561, 592, 658 nm)
- 430-800 nm imaging bandwidth
- Multiple magnifications (60X/.9NA, 40X/.75NA, 20X/.5NA)
- AutoSampler for 96 well plates
- Extended depth of field optics (EDF)

ImageStream[®]X

amnis

IDEAS performs high content morphometric analysis on tens of thousands of images

Cell boundaries are automatically determined.

Identify area of interest on the cell of interest – then apply to all cells

Obtain individual cell data as well as population statistics

Identify subtle shifts in staining patterns

Features are what IDEAS uses to quantify cell morphology.

- 85 features per image

- 16 function masks

- Unlimited number of user defined features

- New features are continually being developed

Multiple levels of analysis – beginner to expert

IDEAS[®] Analysis Software

- High content morphometric analysis of tens of thousands of images
- Application wizards for validated protocols
- “Automated feature finder” quickly finds the best feature for analysis
- 85 parameters per channel, 16 masks, and user defined features for advanced image-based discrimination of cells

Open File	Open ImageStream data files
Apoptosis	Identify apoptotic events based on brightfield and nuclear morphology
Cell Cycle - Mitosis	Distinguish mitotic and apoptotic events
Co-localization	Measure the co-localization of two probes on, in, or between cells
Internalization	Measure the internalization of a probe
Nuclear Localization	Measure the nuclear localization of a probe
Shape Change	Measure circular morphology

THP1 human monocyte cell line treated with intermediate dose of LPS

Here the NFkB / 7-AAD similarity scores are plotted for the sample, and cells with different values are lined up according to their score.

Note that despite the irregularity of the cells, the similarity score accurately reflects the relative nuclear localization of the NFkB in the cells shown, which span a continuum from completely untranslocated (upper left) to nearly completely translocated (upper right)

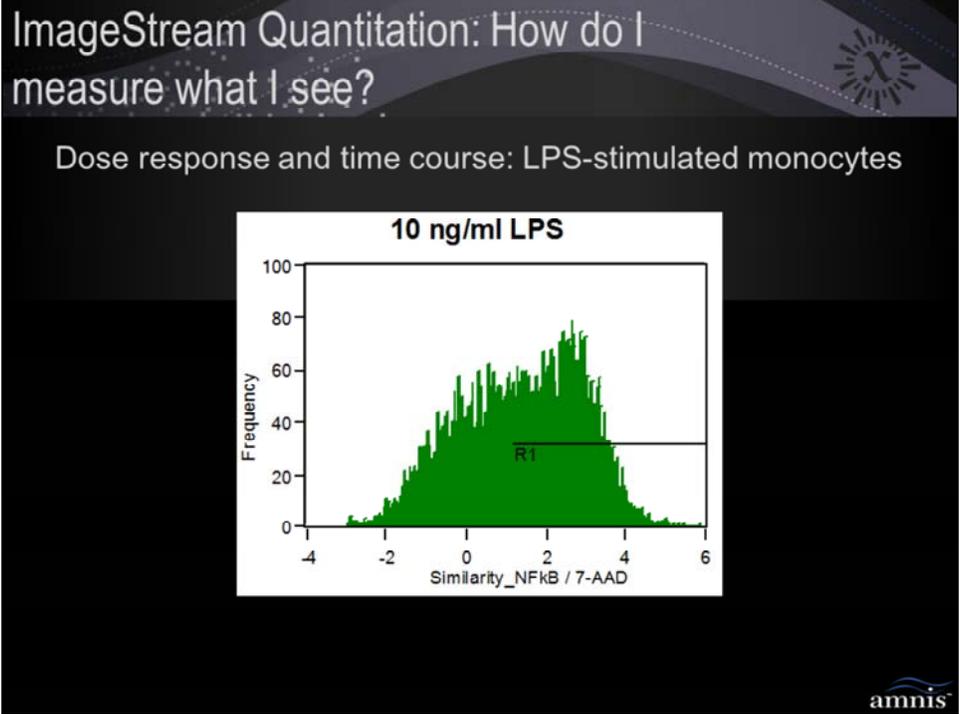

ImageStream Quantitation: How do I measure what I see?

Dose response and time course: LPS-stimulated monocytes

amnis™

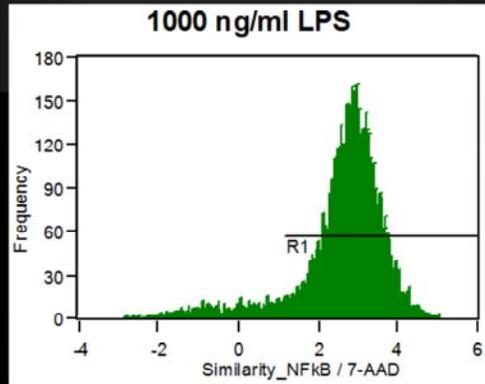

Because we quantify the extent of translocation on a per cell basis, and do this on large sample sizes, we can gate on the percentage of cells translocated per sample. This allows translocation scoring for dose responses and time courses...

How do I best analyze my data?

- IDEAS provides 100s to 1000s of features to choose from
 - 85 base features per image (size, shape, texture, signal strength, location, comparison)
 - 16 masking algorithms
 - Ability to combine masks/features
- Advantage = powerful ability to discriminate different cell types based on their imagery
- Challenge = how to pick the *best* feature(s) that provide the best *statistical separation* between cell types

Dilemma for new user: While IDEAS provides powerful tools to discriminate cells based on their imagery, it is difficult to imagine:

- a) Learning how all the features/mask work
- b) Learning how to apply them to different applications
- c) Choosing the best analysis for an experiment

This is a barrier to adoption of the ImageStream platform

ImageStream as a tool for discriminating cells

Challenge = how to pick the *best* feature(s) that provide the best *statistical separation* between cell types

Task	Human	ImageStream
Design / execute experiment	X	
High speed imaging		X
Identify cells ("truth")	X	
Calculate features and statistics		X
Rank features by discriminating power		X
Interpret / refine result	X	

amnis

To solve the dilemma, it is important to remember that the ImageStream is a TOOL that researchers use.

On a basic level, a tool is a device with properties that enable humans to do a job better than they could by themselves. When you use a tool, you 'collaborate' with it to get the job done. This simply means that you do what you do best and you let the tool do what it does best, and together the job gets done more effectively.

The job = discriminate cells based on their appearance

Tasks:

1 – design and execute experiment = HUMAN; leverage knowledge of the biological system, experimental design, staining protocols, etc

2 – high speed imaging= IMAGESTREAM; leverage high speed camera to take statistically large number of images per sample

3 – identify phenotypes and select truth sets = HUMAN; humans are outstanding at discriminating even subtle differences in imagery. The researcher also usually knows what is expected based on the experiment and can pick them out by hand (ie select 'truth sets' in IDEAS).

4 – Quantify imagery = IMAGESTREAM; humans are horrible at quantifying the differences they see. IDEAS has an extensive set of image-based algorithms and masks designed to discriminate cells based on their appearance; because of the large data sets, IDEAS also provides robust statistics (mean, standard deviation, etc)

5 – Quantify statistical discrimination power of the features, and rank to choose best one = IMAGESTREAM; Use the Rd statistic in IDEAS to measure the discriminating power of each feature; use excel to rank order to choose the best one

6 – Evaluate / refine the result = HUMAN; apply the feature to the whole sample and look for trends in false pos/neg; repick truth if necessary; add advanced features (as you learn the system); protocol development if necessary

Finding the best translocation analysis

Challenge = how to pick the feature that *best* discriminates **untreated** and **LPS-treated** cells

Task	Human	ImageStream
Design / execute experiment	X	
High speed imaging		X
Identify cells ("truth")		
Calculate features and statistics		
Rank features by discriminating power		
Interpret / refine result		

amnis

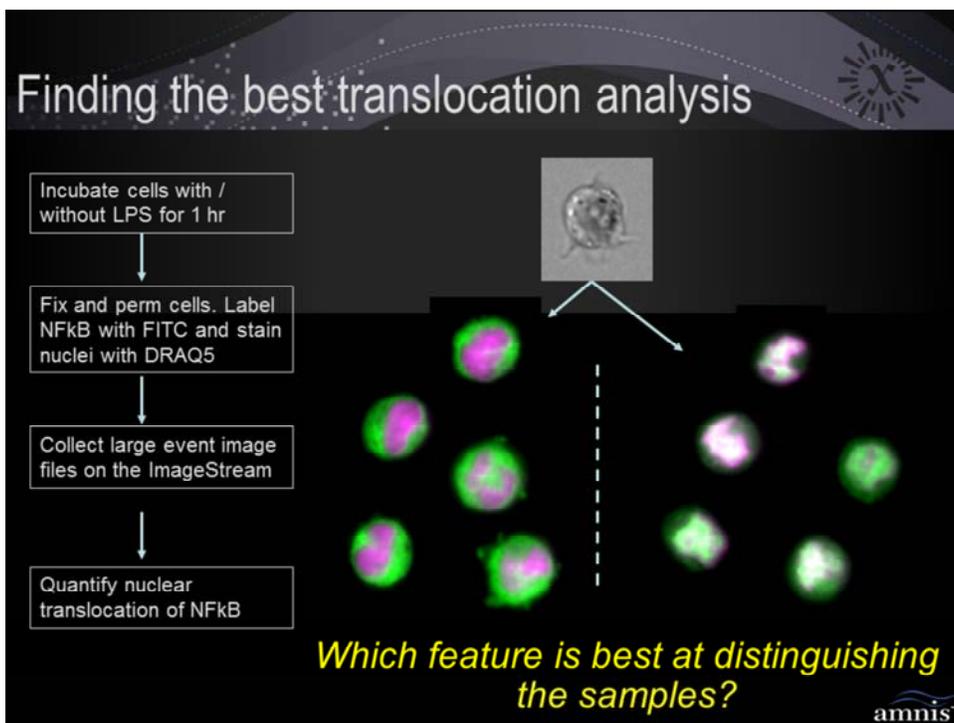

Example number 1: LPS-induced nuc translocation.

The job = Find the best nuclear translocation feature

Tasks:

1 – design and execute experiment = HUMAN; THP-1 cells are incubated with or without a high dose of LPS to activate nuclear translocation of NFkB, then stained with FITC NFkB (green) and DRAQ5 (nuclear dye, red).

2 – high speed imaging= IMAGESTREAM; leverage high speed camera to take statistically large number of images per sample

Example number 1: LPS-induced nuc translocation.

The job = Find the best nuclear translocation feature

Tasks:

1 – design and execute experiment = HUMAN; THP-1 cells are incubated with or without a high dose of LPS to activate nuclear translocation of NFkB, then stained with FITC NFkB (green) and DRAQ5 (nuclear dye, red).

2 – high speed imaging= IMAGESTREAM; leverage high speed camera to take statistically large number of images per sample

Finding the best translocation analysis

Challenge = how to pick the feature that *best* discriminates **untreated** and **LPS-treated** cells

Task	Human	ImageStream
Design / execute experiment	X	
High speed imaging		X
Identify cells ("truth")	X	
Calculate features and statistics		
Rank features by discriminating power		
Interpret / refine result		

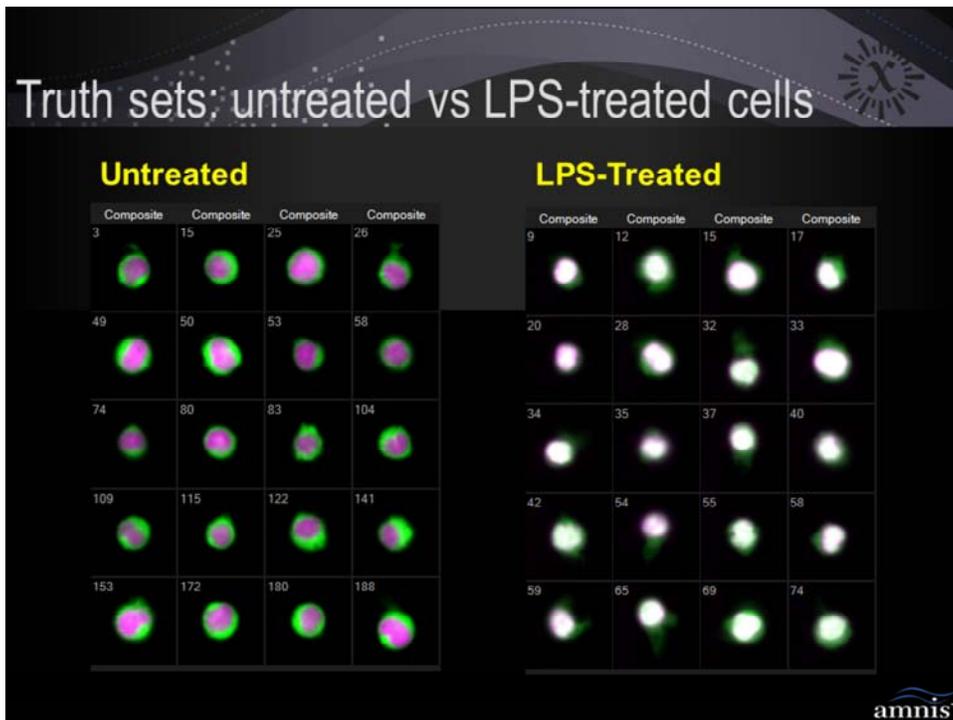

amnis™

Example number 1: LPS-induced nuc translocation.

The job = Find the best nuclear translocation feature

Tasks:

3 – identify phenotypes and select truth sets = HUMAN; in this case, the two samples (untreated vs LPS-treated) will be the truth sets.

Example number 1: LPS-induced nuc translocation.

The job = Find the best nuclear translocation feature

Tasks:

3 – identify phenotypes and select truth sets = HUMAN; in this case, the two samples (untreated vs LPS-treated) will be the truth sets. Note the cytoplasmic distribution of NFkB (green) in the untreated and the nuclear distribution (white) in the LPS-treated

Finding the best translocation analysis

Challenge = how to pick the feature that *best* discriminates **untreated** and **LPS-treated** cells

Task	Human	ImageStream
Design / execute experiment	X	
High speed imaging		X
Identify cells ("truth")	X	
Calculate features and statistics		X
Rank features by discriminating power		X
Interpret / refine result	X	

amnis

Example number 1: LPS-induced nuc translocation.

The job = Find the best nuclear translocation feature

Tasks:

4 – Quantify imagery = IMAGESTREAM; in this example we are hypothetically assuming that IDEAS only has four features (Area, H Variance Mean, Nuc:Cyt NFkB ratio, and Similarity) – this is so we can cover the Rd concept without having to also introduce concept of how to create/handle huge feature sets right off the bat

5 – Quantify statistical discrimination power of the features, and rank to choose best one = IMAGESTREAM; Use the Rd statistic in IDEAS to measure the discriminating power of each feature; use excel to rank order to choose the best one

6 – Evaluate / refine the result = HUMAN; apply the feature to the whole sample and look for trends in false pos/neg; repick truth if necessary; add advanced features (as you learn the system); protocol development if necessary

Finding the best translocation analysis

- Four Features for translocation:
 - **Brightfield Area**
 - Measures change in cell size
 - Not expected to be useful
 - **H Variance Mean_NFkB**
 - Measures change in NFkB texture or pattern
 - Does not require mask
 - **Nuc:Cytoplasmic NFkB Ratio**
 - Measures comparative amount of NFkB in the nucleus and cytoplasm
 - Most intuitive
 - **Similarity_NFkB/DRAQ5**
 - Measures increasing similarity of NFkB and DRAQ5 images as NFkB moves to the nucleus
 - Amnis [claims](#) this is the best feature

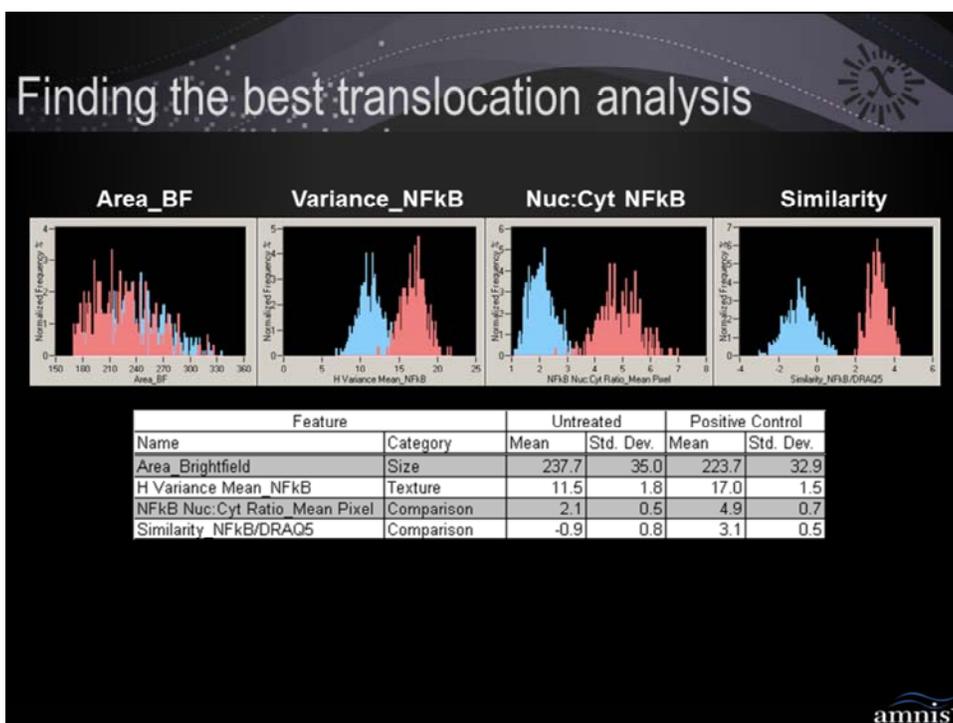

Example number 1: LPS-induced nuc translocation.

The job = Find the best nuclear translocation feature

Tasks:

4 – Quantify imagery = IMAGESTREAM; in this example we are hypothetically assuming that IDEAS only has four features (Area, H Variance Mean, Nuc:Cyt NFkB ratio, and Similarity) – this is so we can cover the Rd concept without having to also introduce concept of how to create/handle huge feature sets right off the bat

Example number 1: LPS-induced nuc translocation.

The job = Find the best nuclear translocation feature

Tasks:

5 – Quantify statistical discrimination power of the features, and rank to choose best one = IMAGESTREAM;

Here we can QUALITATIVELY assess the discrimination power of the 4 features by looking at the overlap between the untreated (blue) and treated (red) histograms. Area looks the worst; Variance is pretty good but not as good as Nuc:Cyt Ratio or Similarity, and it is difficult to tell which of the latter two is the best

Finding the best translocation analysis

Challenge = how to pick the *best* feature(s) that provide the best *statistical separation* between cell types

Task	Human	ImageStream
Design / execute experiment	X	
High speed imaging		X
Identify cells ("truth")	X	
Calculate features and statistics		X
Rank features by discriminating power		X
Interpret / refine result	X	

Key to statistically determining the best feature that discriminates the hand-picked cells is the discrimination statistic (R_d) which is explained on the next slide...

Rd - statistical measure of discrimination

Fisher's Discriminant ratio (Rd)

- Measure of the statistical separation a feature provides between two populations (1&2) using their means and standard deviations:

$$Rd = (\text{Mean}_1 - \text{Mean}_2) / (\text{StdDev}_1 + \text{StdDev}_2)$$

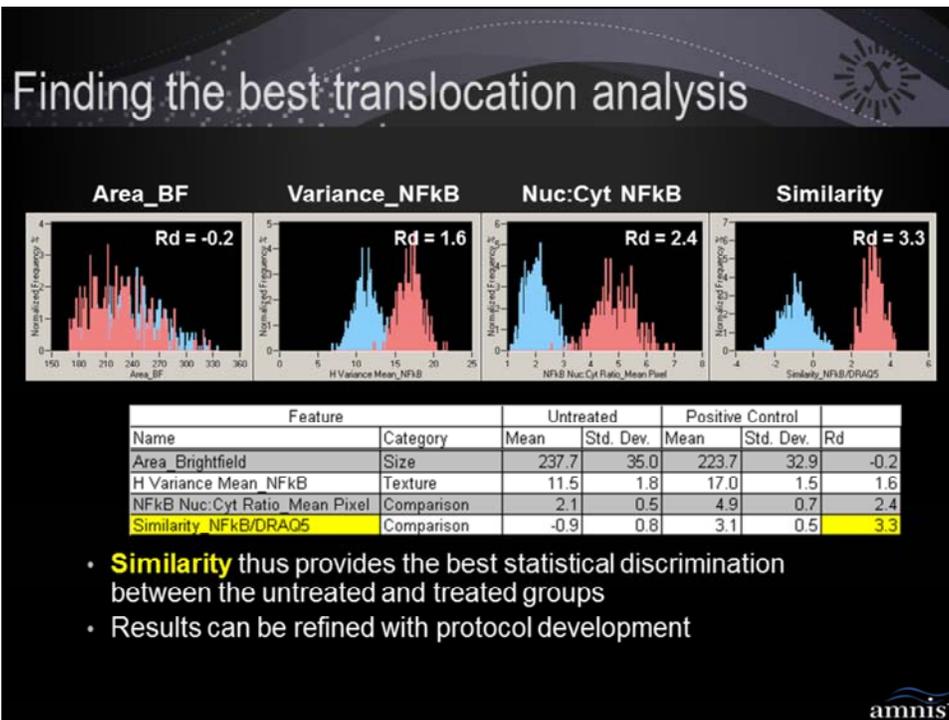

- Note that discriminating power increases with increasing mean differences and decreasing standard deviations
- Populations 1&2 can be:
 - Different samples
 - Different hand-picked truth sets
 - Same set of cells analyzed with different features

Key to statistically determining the best feature that discriminates the hand-picked cells is the discrimination statistic which is called:

Fisher's Discriminant Ratio (Rd):

This statistic measures how much separation a particular feature provides between two populations

Example number 1: LPS-induced nuc translocation.

The job = Find the best nuclear translocation feature

Tasks:

5 – Quantify statistical discrimination power of the features, and rank to choose best one = IMAGESTREAM;

Here we can QUANTITATIVELY assess the discrimination power of the 4 features by ranking the Rd. Doing so allows us to determine that Similarity is the best

6 – Evaluate / refine the result = HUMAN; in this example, there are no other possible features, so unless there is a concern with the truth populations, there is no need to refine those. Changes to the protocol (diff stains, diff fix/perm, diff incubation times, etc) could be tried to improve the separation, and in these cases, the protocol that provided the greatest Rd Similarity would be chosen as the best protocol.

Thus, the ImageStream is an excellent tool for protocol development, as it provides you with tools to visualize, hand select, gate, quantify your cells of

interest and can measure statistical separation

Finding the best translocation analysis

Conclusion: *Similarity* provides the **best statistical discrimination** between the untreated and LPS-treated groups

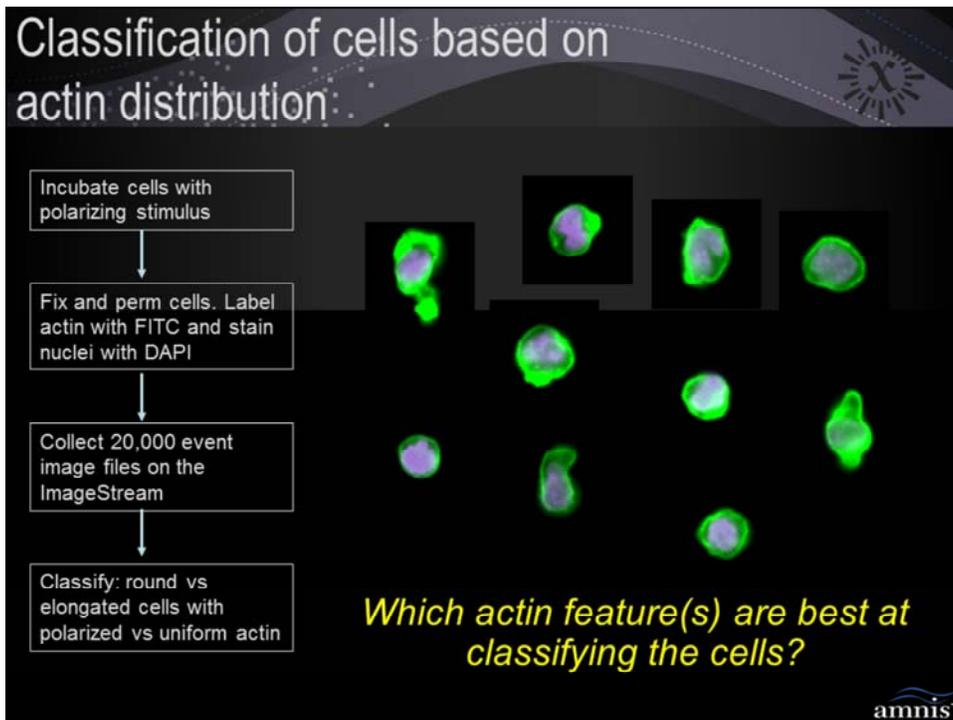

Task	Human	ImageStream
Design / execute experiment	X	
High speed imaging		X
Identify cells ("truth")	X	
Calculate features and statistics		X
Rank features by discriminating power		X
Interpret / refine result	X	

amnis™

Example number 1: LPS-induced nuc translocation.

The job = Find the best nuclear translocation feature

Conclusion = SIMILARITY

Example number 2: Treatment-induced change in actin distribution

Cell line incubated with compound to induce changes in actin, then stained with FITC phalloidin (actin, green) and DAPI (nuclear dye, purple).

The job = classify cells based on their actin morphology

Tasks:

1 – design and execute experiment = HUMAN; leverage knowledge of the biological system, experimental design, staining protocols, etc

2 – high speed imaging= IMAGESTREAM; leverage high speed camera to take statistically large number of images per sample

Classification of cells based on actin distribution:

Challenge = how to pick the feature(s) that *best* discriminate cells with *differences in actin* distribution

Task	Human	ImageStream
Design / execute experiment	X	
High speed imaging		X
Identify cells ("truth")	X	
Calculate features and statistics		
Rank features by discriminating power		
Interpret / refine result		

amnis™

Example number 2: Treatment-induced change in actin distribution

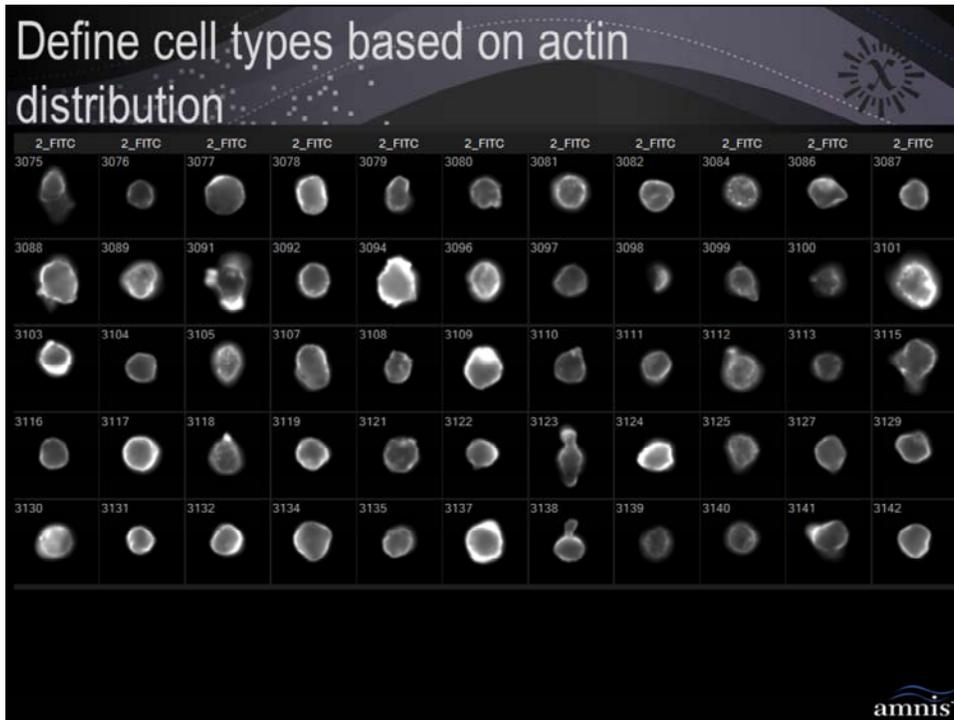

Cell line incubated with compound to induce changes in actin, then stained with FITC phalloidin (actin, green) and DAPI (nuclear dye, purple).

The job = classify cells based on their actin morphology

Tasks:

1 – design and execute experiment = HUMAN; leverage knowledge of the biological system, experimental design, staining protocols, etc

2 – high speed imaging= IMAGESTREAM; leverage high speed camera to take statistically large number of images per sample

Example number 2: Treatment-induced change in actin distribution

Cell line incubated with compound to induce changes in actin, then stained with FITC phalloidin (actin, green) and DAPI (nuclear dye, purple).

The job = classify cells based on their actin morphology

Tasks:

3 – identify phenotypes and select truth sets = HUMAN; Panel of images showing some differences. Can see a couple of patterns:

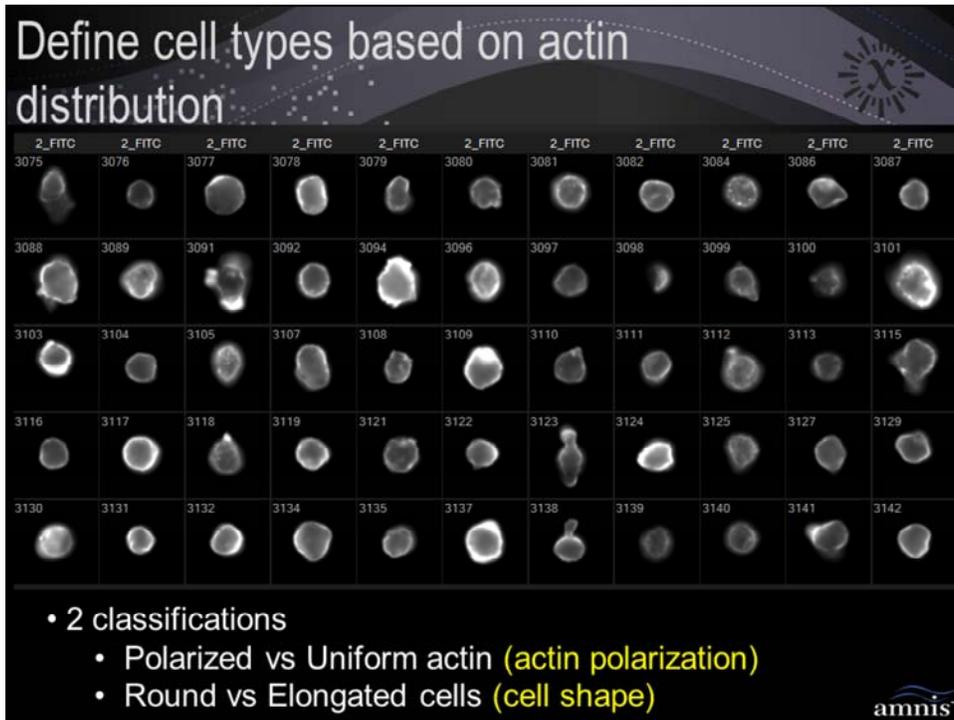

1 – shape: some cells are round (3077, 3087, 3117, 3137, etc) while some are elongated (3123, 3138).

2 – polarity: some have uniformly distributed actin (3076, 3078, 3242, etc) while some have polarized actin (3103, 3109, etc)

Thus, we will create 4 truth populations, and pair them to find a best feature to discriminate shape and a best feature to discriminate polarity

THIS IS AN IMPORTANT FIRST STEP TO ANY IMAGESTREAM

EXPERIMENT as it gives you an idea of how well the experiment worked, and how much discrimination you can expect IDEAS to find for you. If you don't see enough differences to define truth, then you probably want to revisit the protocol...

Example number 2: Treatment-induced change in actin distribution

Cell line incubated with compound to induce changes in actin, then stained with FITC phalloidin (actin, green) and DAPI (nuclear dye, purple).

The job = classify cells based on their actin morphology

Tasks:

3 – identify phenotypes and select truth sets = HUMAN; Panel of images showing some differences. Can see a couple of patterns:

1 – shape: some cells are round (3077, 3087, 3117, 3137, etc) while some are elongated (3123, 3138).

THIS IS AN IMPORTANT FIRST STEP TO ANY IMAGESTREAM

EXPERIMENT as it gives you an idea of how well the experiment worked, and how much discrimination you can expect IDEAS to find for you. If you don't see enough differences to define truth, then you probably want to revisit the protocol...

Example number 2: Treatment-induced change in actin distribution

Cell line incubated with compound to induce changes in actin, then stained with FITC phalloidin (actin, green) and DAPI (nuclear dye, purple).

The job = classify cells based on their actin polarity

Tasks:

3 – identify phenotypes and select truth sets = HUMAN; Cells with uniform actin – the cells chosen ‘span the range’ of examples with uniform actin, including dim and bright, round and elongated, small and large. Same holds for the polarized truth. This method of choosing cells that ‘span the range’ ensure that the feature that wins is indeed a measure of polarity (and not size, shape, etc)

Classification of cells based on actin distribution:

Challenge = how to pick the feature(s) that *best* discriminate cells with **differences in actin** distribution

Task	Human	ImageStream
Design / execute experiment	X	
High speed imaging		X
Select truth sets	X	
Calculate features and statistics		X
Rank features by discriminating power		X
Interpret / refine result	X	

amnis™

Example number 2: Treatment-induced change in actin distribution

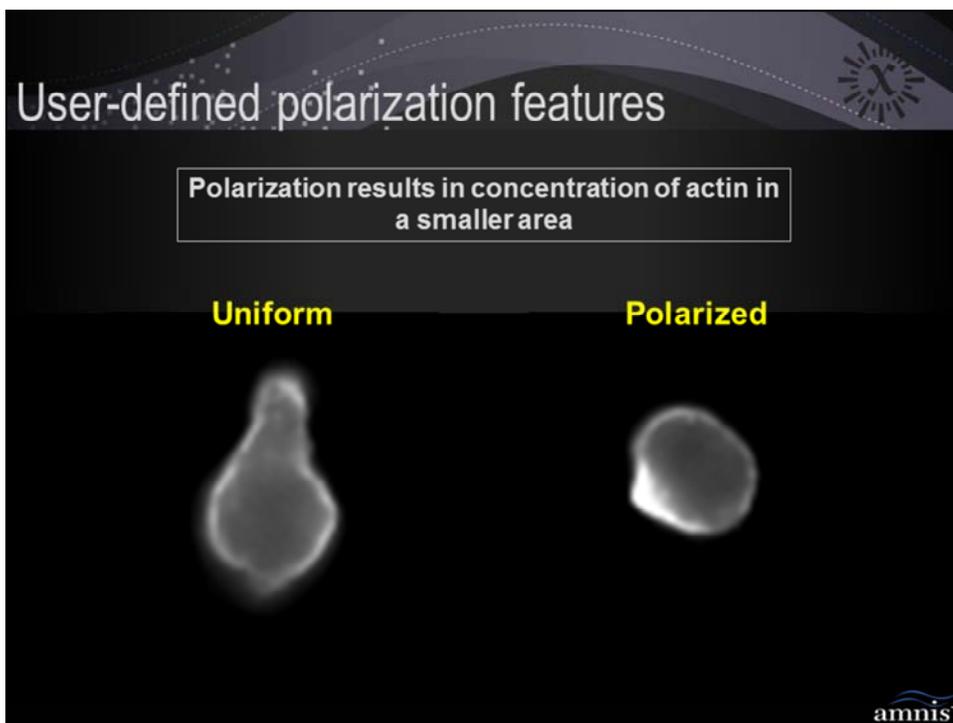

Cell line incubated with compound to induce changes in actin, then stained with FITC phalloidin (actin, green) and DAPI (nuclear dye, purple).

The job = classify cells based on their actin polarity

Tasks:

4 – Quantify imagery = IMAGESTREAM; humans are horrible at quantifying the differences they see. Here we will show how to get IDEAS to calculate multiple features and to export the Rd statistic for ranking in Excel

5 – Quantify statistical discrimination power of the features, and rank to choose best one = IMAGESTREAM; Use the Rd statistic in IDEAS to measure the discriminating power of each feature; use excel to rank order to choose the best one

Example number 2: Treatment-induced change in actin distribution

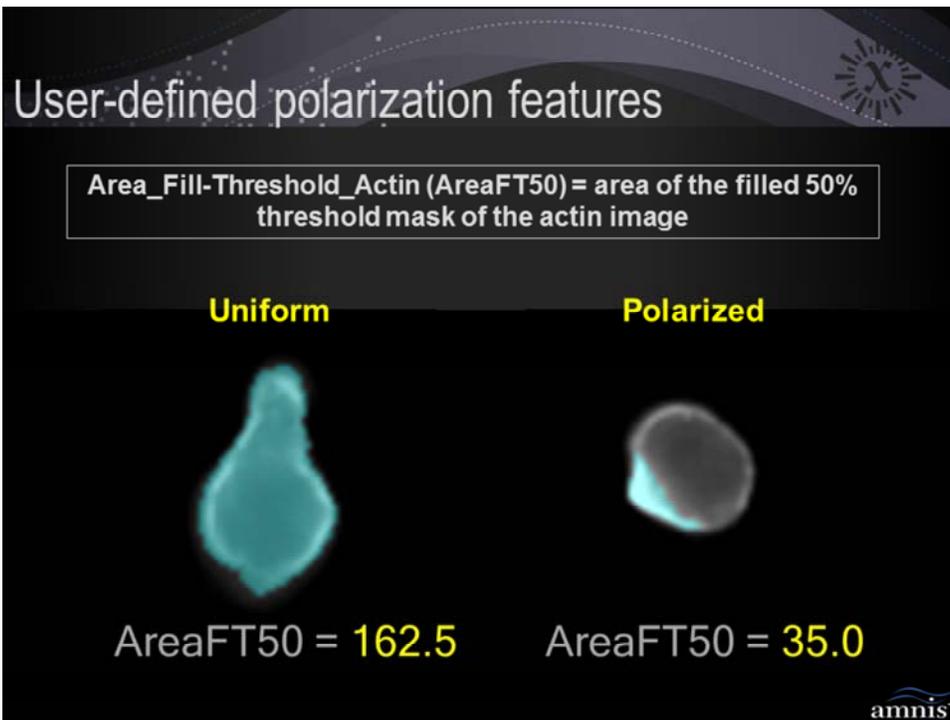

Cell line incubated with compound to induce changes in actin, then stained with FITC phalloidin (actin, green) and DAPI (nuclear dye, purple).

The job = classify cells based on their actin polarity

Tasks:

4 – Quantify imagery = IMAGESTREAM; humans are horrible at quantifying the differences they see, but lets try to do it anyway:

To do this, we try to imagine a way to numerically score the difference in actin polarity between these two images. With a bit of training, we know that a threshold mask can be generated that will just mask the brightest portion of the image. Because the image on the right has concentrated actin in a small area, the area of the threshold mask is expected to be lower than the image on the left.

Example number 2: Treatment-induced change in actin distribution

Cell line incubated with compound to induce changes in actin, then stained with FITC phalloidin (actin, green) and DAPI (nuclear dye, purple).

The job = classify cells based on their actin polarity

Tasks:

4 – Quantify imagery = IMAGESTREAM; humans are horrible at quantifying the differences they see, but lets try to do it anyway:

To do this, we try to imagine a way to numerically score the difference in actin polarity between these two images. With a bit of training, we know that a threshold mask can be generated that will just mask the brightest portion of the image. Because the image on the right has concentrated actin in a small area, the are of the threshold mask is expected to be lower than the image on the left.

Here we show the area of the Filled 50% actin threshold mask for both cells. So this feature provides good separation FOR THESE TWO CELLS. At this point we would need a way to evaluate this feature on more cells to see if the thresholding we did was best...

User-defined polarization features

- Risks for the single, user-defined feature approach:
 - Did I choose the right mask for the area feature?
 - Which threshold mask is best?
 - Is filling the mask the right thing to do?
 - Is there some other feature that is better than area of a threshold mask?
- Solution: let IDEAS help!
 - Make area features with several mask inputs
 - Make multiple actin features using common masks (default, object, morphology)
 - Export features to excel for Rd-based feature selection

Example number 2: Treatment-induced change in actin distribution

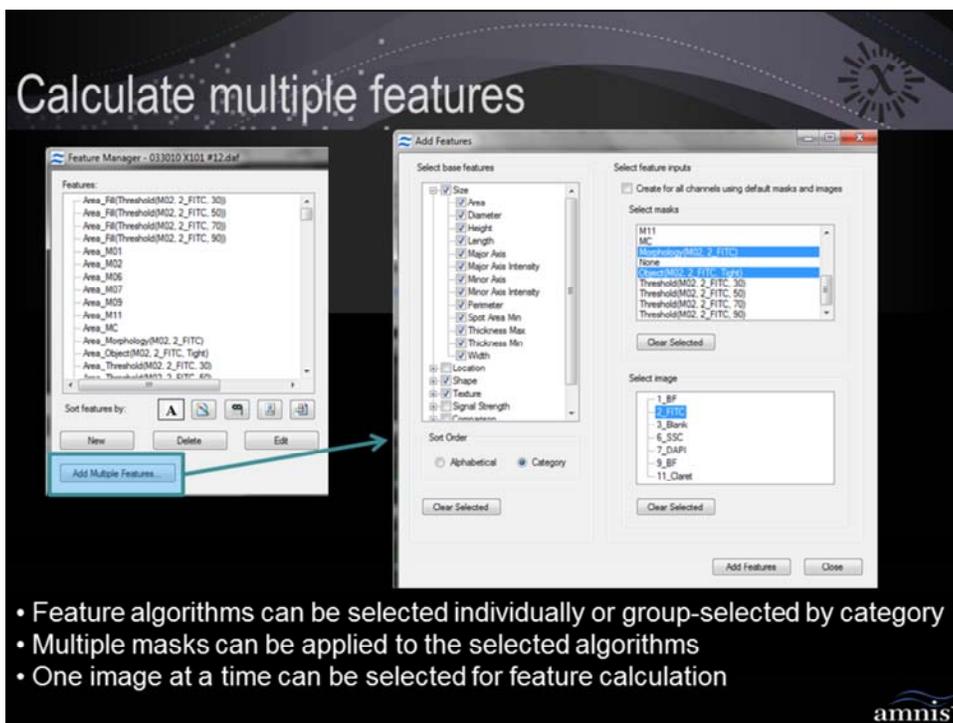

Cell line incubated with compound to induce changes in actin, then stained with FITC phalloidin (actin, green) and DAPI (nuclear dye, purple).

The job = classify cells based on their actin polarity

Tasks:

4 – Quantify imagery = IMAGESTREAM;

By trying to quantify the imagery all by ourselves, we are trying to do what the ImageStream is best at (namely, calculating tons of image-based features for all cells and measuring statistical separation), and by doing so, we are looking for a needle in a haystack. At this point, a little teamwork is in order. You can help create some smarter features by applying all masks that you think will help, like the threshold mask (since you don't know what threshold %, make several threshold masks, each with a different %), and the simple cellular masks (default, object, morphology) to the actin channel. Then let IDEAS calculate all the features and statistics necessary to find the one that best separates your truth sets.

Example number 2: Treatment-induced change in actin distribution

Cell line incubated with compound to induce changes in actin, then stained with FITC phalloidin (actin, green) and DAPI (nuclear dye, purple).

The job = classify cells based on their actin polarity

Tasks:

4 – Quantify imagery = IMAGESTREAM;

This slide shows the interface for rapidly instructing IDEAS to calculate multiple features...Apply all masks that you think will help, like the threshold mask (since you don't know what threshold %, make several threshold masks, each with a different %), and the simple cellular masks (default, object, morphology) to the actin channel. Then let IDEAS calculate all the features and statistics necessary to find the one that best separates you truth sets.

Note, you can also limit the features to calculate by category (ie maybe you just want a shape feature), by mask, by channel, by base feature...

Rd Mean stats from IDEAS

- Add population stats from the pop stats context menu
- Select 'polarized' for stats population and 'uniform' for reference population
- Select 'Rd - Mean' for the statistic
- Sort features by image and select the FITC actin image features
- Export to excel and sort data by Rd

Example number 2: Treatment-induced change in actin distribution

Cell line incubated with compound to induce changes in actin, then stained with FITC phalloidin (actin, green) and DAPI (nuclear dye, purple).

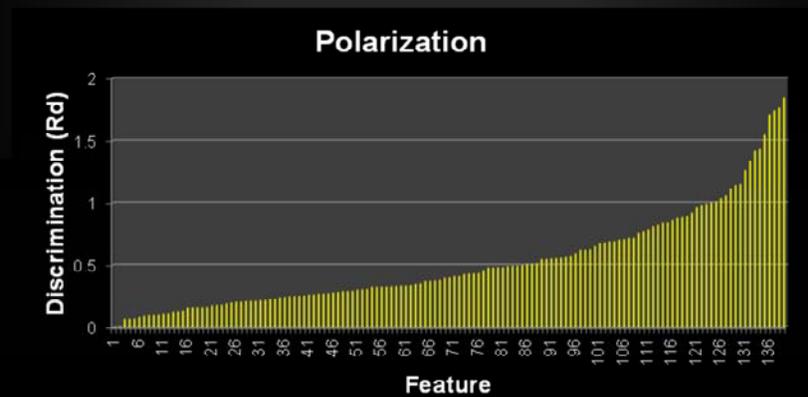

The job = classify cells based on their actin polarity

Tasks:

5 – Quantify statistical discrimination power of the features, and rank to choose best one = IMAGESTREAM; Use the Rd statistic in IDEAS to measure the discriminating power of each feature; use excel to rank order to choose the best one

This slide shows how to export the Rd-mean statistic for the actin features (polarized vs uniform)

Polarized vs Uniform actin – best feature

Polarization features (x-axis) ranked by discrimination power (Rd, y-axis)

amnis™

Example number 2: Treatment-induced change in actin distribution

Cell line incubated with compound to induce changes in actin, then stained with FITC phalloidin (actin, green) and DAPI (nuclear dye, purple).

The job = classify cells based on their actin polarity

Tasks:

5 – Quantify statistical discrimination power of the features, and rank to choose best one = IMAGESTREAM; This is a plot of IDEAS actin polarization features (X-axis) vs. Discrimination power (Rd, Y-axis). Data for ~140 features are shown. The feature with the highest Rd will be chosen...

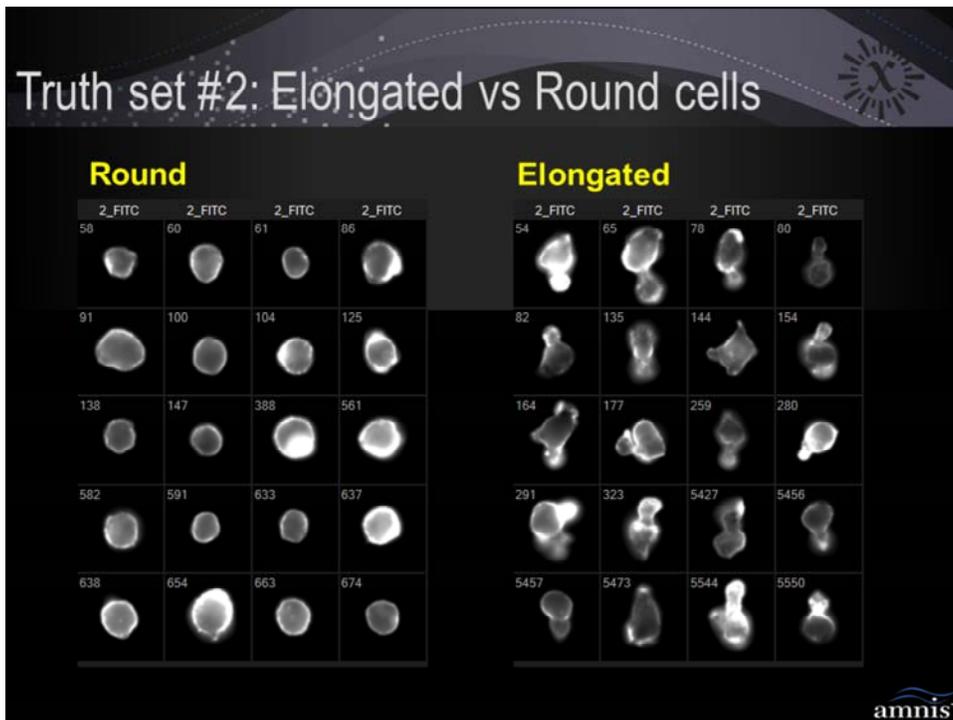

Example number 2: Treatment-induced change in actin distribution

Cell line incubated with compound to induce changes in actin, then stained with FITC phalloidin (actin, green) and DAPI (nuclear dye, purple).

The job = classify cells based on their actin polarity

Tasks:

5 – Quantify statistical discrimination power of the features, and rank to choose best one = IMAGESTREAM; Top-20 actin polarization features are shown. The feature with the highest Rd is **Area_FT70%** and represents the feature that provides the best statistically discrimination between the uniform and polarized **TRUTH** sets. Note, the feature that wins is critically dependent on the truth sets, and if upon evaluation of the feature on the larger file it is found that the feature does not perform well, you may need to refine the truth sets and repeat the process...

Example number 2: Treatment-induced change in actin distribution

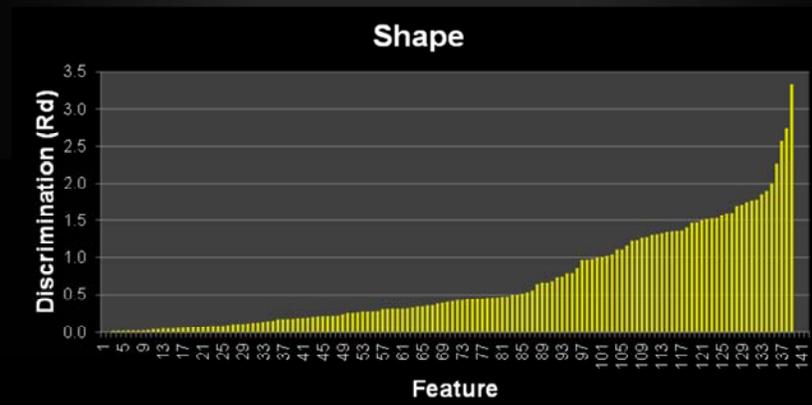

Cell line incubated with compound to induce changes in actin, then stained with FITC phalloidin (actin, green) and DAPI (nuclear dye, purple).

The job = classify cells based on their shape

Tasks:

3 – identify phenotypes and select truth sets = HUMAN; Round vs Elongated truth – the cells chosen ‘span the range’ of examples, including dim and bright, small and large, uniform and polarized. This method of choosing cells that ‘span the range’ ensure that the feature that wins is indeed a measure of polarity (and not size, polarity, etc)

Elongated vs Round cells – best feature

Shape features (x-axis) ranked by discrimination power (Rd, y-axis)

ImageStream Cytometry: Discriminating cells based on appearance

- Results are backed by **statistics**
- **Defend images** (not algorithms)
- Applicable at **any ability level** and scales with ability
- You learn features / functions **relevant to your application**
- **Protocol development tool**
- **Publishable**
- **AGNOSTIC** to application and discipline

Results backed by statistics:

feature with best statistical discrimination power selected from a large list of competitors)

Defend images not algorithms:

you don't need to know what the math behind the algorithm to defend it in front of peers – just defend the truth populations. This places the debate within the arena where humans work best, ie qualitatively discriminating cells that represent the expected biology, as opposed to arguing about complicated math problems...)

Applicable by all ability levels and scales with ability:

With this process, you can get statistically defensible (and publishable) results before you learn any of the algorithms. As you learn more advanced operations, you can add new functions/features to the list for Rd ranking, potentially improving the results...

You learn features/functions relevant to your application:

Instead of trying to learn all 85 features and 16 masking functions at once, this

process points you to the features that work best in your system – you learn these first. As you refine the truth, you learn advanced operations that improve your top features...

Protocol development tool:

Protocol development is made easy using this system – two major reasons: First, you can see your cells for quick qualitative assessment of success/failure of experimental design (negative and positive biologic controls, stains, fix/perm, etc). Second, the discriminant ratio can be employed to quantify the effect of any protocol change. For example, if you compare triton perm vs saponin perm for nuc trans assay, you choose the perm that provides the highest Rd Similarity between the untreated and treated samples.

Publishable:

ImageStream technology is relatively new – many (if not most) new protocols you develop with the system will be novel and publishable.

Agnostic to application and discipline:

As long as your experiment results in populations of cells that can be differentiated by the ImageStream, this process will find features that discriminate the populations

ImageStream Cytometry: Discriminating cells based on appearance

Cell signaling

Cell death & autophagy

Internalization & phagocytosis

DNA damage and repair

Surface and intracellular co-localization

Stem cell biology

Shape change & chemotaxis

Oceanography

Cell-cell interaction

Microbiology

Cell cycle & mitosis

Parasitology

ImageStream Cytometry: Discriminating cells based on appearance

Thank you very much for your attention
